(57) **ABSTRACT**

An icemaker is mounted remotely from a freezer compart-
ment. The icemaker includes an ice mold. A thermoelectric
device is provided and includes a warm side and an opposite
cold side. A flow pathway is connected in communication
between the cold side of the thermoelectric device and the
icemaker. In one aspect, a fan is operatively positioned to
move air from the fresh food compartment across the warm
side of the thermoelectric device and a pump moves fluid
from the cold side of the thermoelectric device to the ice-
maker. Cold air, such as from a refrigerator compartment,
may be used to dissipate heat from the warm side of the
thermoelectric device for providing cold fluid to and for cool-
ing the ice mold of the icemaker.

REFRIGERATOR WITH ICEMAKER CHILLED BY THERMOELECTRIC DEVICE COOLED BY FRESH FOOD COMPARTMENT AIR

FIELD OF THE INVENTION

The invention relates generally to refrigerators with ice-makers, and more particularly to refrigerators with the ice-maker located remotely from the freezer compartment.

BACKGROUND OF THE INVENTION

Household refrigerators commonly include an icemaker to automatically make ice. The icemaker includes an ice mold for forming ice cubes from a supply of water. Heat is removed from the liquid water within the mold to form ice cubes. After the cubes are formed they are harvested from the ice mold. The harvested cubes are typically retained within a bin or other storage container. The storage bin may be operatively associated with an ice dispenser that allows a user to dispense ice from the refrigerator through a fresh food compartment door.

To remove heat from the water, it is common to cool the ice mold. Accordingly, the ice mold acts as a conduit for removing heat from the water in the ice mold. When the ice maker is located in the freezer compartment this is relatively simple, as the air surrounding the ice mold is sufficiently cold to remove heat and make ice. However, when the icemaker is located remotely from the freezer compartment, the removal of heat from the ice mold is more difficult. Therefore, the proceeding disclosure provides improvements over existing designs.

SUMMARY OF THE INVENTION

According to one exemplary aspect, a refrigerator that has a fresh food compartment, a freezer compartment, and a door that provides access to the fresh food compartment is disclosed. An icemaker is mounted remotely from the freezer compartment. The icemaker includes an ice mold. Also included is a thermoelectric device. The thermoelectric device has a warm side and an opposite cold side. A flow path is connected in communication between the cold side of the thermoelectric device and the icemaker and a fan is positioned to move air from the fresh food compartment across the warm side of the thermoelectric device. A fluid loop on the door is configured in communication between the thermoelectric device and the icemaker supplies cold fluid to the ice mold from the thermoelectric device. According to another aspect, an insulated compartment may also be included on the door. An ice storage bin within the insulated compartment is positioned to receive ice harvested from the ice mold. A flow path is positioned in communication between the insulated compartment and thermoelectric device for cooling the insulated compartment housing the ice storage bin.

According to another exemplary aspect, a refrigerator having a fresh food compartment, a freezer compartment and a door that provides access to the fresh food compartment is disclosed. The refrigerator includes an icemaker mounted remotely from the freezer compartment. The icemaker includes an ice mold. A thermoelectric device is used that includes a warm side and opposite cold side. A pump is positioned to move fluid from the cold side of the thermoelectric device to the icemaker and a fan is positioned to move air from the fresh food compartment across the warm side of the thermoelectric device. A heat exchange interface may be

2

provided between the fluid supply pathway and a cooling application on the door or a fluid return pathway and a warming application on the door.

According to another exemplary aspect, a device with a cabinet body having an icemaker with an ice mold chilled at least partially by a thermoelectric device is disclosed. The device includes an icemaker module having an icemaker with an ice mold selectively positioned within the cabinet body for providing ice to an ice receiving area. A thermoelectric device is positioned on the icemaker module. The thermoelectric device has a cold side and a warm side. A first pathway may be configured to move a heat carrier between the cold side of the thermoelectric device and the icemaker and a second pathway may be configured to move a heat carrier across the warm side of the thermoelectric device.

BRIEF DESCRIPTION OF THE DRAWINGS

While the specification concludes with claims particularly pointing out and distinctly claiming the invention, it is believed that the various exemplary aspects of the invention will be better understood from the following description taken in conjunction with the accompanying drawings, in which:

FIG. 1A is a perspective view of a refrigerator in accordance with an exemplary aspect of the invention;

FIG. 1B is a perspective view of a refrigeration platform in accordance with an exemplary aspect of the invention;

FIG. 1C is a perspective view of another refrigeration platform in accordance with an exemplary aspect of the invention;

FIG. 1D is a perspective view of another refrigeration platform in accordance with an exemplary aspect of the invention;

FIG. 2 is a side elevation of a sectional view of the refrigerator shown in FIG. 1;

FIG. 3 is a perspective view with a cutaway illustrating various exemplary aspects within the refrigerator on the door of the refrigerator in accordance with an aspect of the invention;

FIG. 4 is a perspective view of the inside of a door of the refrigerator according to one exemplary aspect of the invention;

FIG. 5 is a perspective view of the inside of a door of the refrigerator according to another exemplary aspect of the present;

FIG. 6 is a perspective view of the inside of a door of the refrigerator in accordance with an exemplary aspect of the invention;

FIG. 7 is a perspective view of the inside of a door of the refrigerator according to another exemplary aspect of the invention;

FIG. 8 is a perspective view of the inside of a door of the refrigerator for an exemplary aspect of the invention; and

FIG. 9 is a diagram illustrating exemplary control aspects of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

By way of illustration, FIGS. 1-9 provide exemplary features, aspects and embodiments for a refrigerator 10 of the present invention. The refrigerator 10 includes a cabinet body 12 with a refrigerator compartment or fresh food compartment 14 selectively closeable by a refrigerator compartment door 18 and a freezer compartment 16 selectably closeable by a freezer compartment door 20. A dispenser 22 is included on

the refrigerator compartment door **18** for providing dispensations of liquid and/or ice at the refrigerator compartment door **18**. Although one particular design of a refrigerator **10** is shown in FIG. 1A and replicated throughout various figures of the present invention, other refrigerator styles and configurations are contemplated. For example, the refrigerator **10** could be a side-by-side refrigerator, a refrigerator with the freezer compartment positioned above the refrigerator compartment (top-mount refrigerator), a refrigerator with the freezer compartment positioned beneath the refrigerator compartment (bottom-mount refrigerator), a refrigerator that includes only a refrigerator or fresh food compartment and no freezer compartment, etc. In the figures is shown a bottom-mount refrigerator **10** where the freezer compartment **16** is located below the refrigerator compartment **14**. The concepts of the present invention may also be incorporated into other refrigerated platforms. For example, a water dispenser/cooler **10** (See FIG. 1B), a countertop dispenser **10** (See FIG. 1C), an under-counter dispenser **10** (See FIG. 1D) may be configured with one or more aspects of the present invention.

Several aspects of the present invention are illustrated in the sectional and cutout views of refrigerator **10** shown in FIGS. 2 and 3. In connection with the dispenser **22** on the cabinet body **12** of the refrigerator **10**, such as for example on the refrigerator compartment door **18**, is an icemaker **102** having an ice mold **106** for extracting heat from liquid within the ice mold to create ice which is dispensed from the ice mold **106** into an ice storage bin **104**. The ice is stored in the ice storage bin **104** until dispensed from the dispenser **22**. The ice mold **106** or icemaker **102** may include a fluid sink (not shown) for extracting heat from the ice mold **106** using a fluid as the extraction medium. The present invention also contemplates that air may be used as the medium for carrying away heat from the ice mold **106**. According to one aspect of the present invention, a fluid supply pathway **110** is connected between the icemaker **102** and a thermoelectric device **50**. A fluid return pathway **112** is also connected between the icemaker **102** and the thermoelectric device **50**. The fluid supply pathway **110** and the fluid return pathway **112** together form a fluid loop connecting the icemaker **102** with the thermoelectric device **50**. The fluid supply pathway **110** and fluid return pathway **112** could also be configured as air pathways (e.g., an air supply pathway and an air return pathway) connected between the icemaker **102** and thermoelectric device **50**. The pathways **110**, **112** may include a conduit, line, ductwork, or other enclosed flow path to facilitate the transfer of a heat carrying medium (e.g., fluid or air) between the icemaker **102** and the thermoelectric device **50**. In one aspect of the invention, fluid supply pathway **110** and fluid return pathway **112** are connected to a fluid sink **58** positioned on the cold side **54** of the thermoelectric device **50**. The fluid sink **58** provides a thermal transfer pathway between the fluid carrier and the cold side **54** of the thermoelectric device **50**. The fluid in the line between the icemaker **102** and the thermoelectric device **50** may be a heat transfer fluid such as ethylene or propylene glycol. The fluid in the line between the icemaker **102** and the thermoelectric device **50** may be a heat transfer fluid such as ethylene or propylene glycol. As the fluid temperature may drop below freezing, it may be beneficial to use an anti-freeze, such as glycol, such that the fluid will not freeze when passing through the fluid pathways **110**, **112**. The fluid in the fluid pathways could also be water or other chemically altered fluid suitable for use in combination with food.

The cold side **54** of the thermoelectric device **50** is kept generally at a temperature below the temperature required for making ice (e.g., temperatures near or below 0° Fahrenheit). Conversely, the warm side **52** of the thermoelectric device **50**

is operated at a temperature of the desired temperature for the fluid used to cool the ice mold plus the operating delta for the thermoelectric device **50**. For example, if the delta for the thermoelectric device **50** is 20° Fahrenheit, the warm side **52** of the thermoelectric device **50** must be kept at a temperature less than 52° Fahrenheit to maintain the cold side **54** of the thermoelectric device **50** at 32° Fahrenheit or below. An electrical current is provided to the thermoelectric device **50** which provides the necessary Peltier effect that creates a heat flux and provides a cold side **54** and warm side **52** during operation. To dissipate heat from the warm side **52** of the thermoelectric device **50**, an air sink **56** is configured in operable thermal operation with the warm side **52** of the thermoelectric device **50**. An air supply pathway **62** is connected between the air sink **56** and a fan **60** positioned within the refrigerator compartment **14** of the refrigerator **10**. An air return pathway **64** is connected between the air sink **56** and the refrigerator compartment **14** and/or freezer compartment **16**, wherein flow there through is selectably open and closed by operation of flow controller **80**. In a typical refrigerator, the refrigerator compartment **14** is kept generally between 32° Fahrenheit and about 40° Fahrenheit. A fan **60** or other means (e.g., pump) for moving air through a ductwork or other channel is positioned within the refrigerator compartment **14** at a location such as adjacent the mullion that separates the refrigerator compartment **14** from the freezer compartment **16**. Other embodiments are contemplated. For example, the fan **60** may be positioned within a mullion or sidewall of the cabinet body **12** of the refrigerator **10**. Advantageously, positioning the fan **60** adjacent the horizontal mullion that separates the refrigerator compartment from the freezer compartment draws cooler air within the refrigerator compartment **14** given that the cooler air within the refrigerator compartment **14** is generally located closer to or adjacent the horizontal mullion that separates the refrigerator compartment **14** from the freezer compartment **16**. The cool air may be ducted out of the refrigerator compartment **14** through an air supply pathway **62** using fan **60**. The fan may also be positioned within the insulated compartment **108** on the refrigerator compartment door **18**. The cool air pumped to the air sink **56** at the thermoelectric device **50** may be exhausted back into the refrigerator compartment **14** or into the freezer compartment **16**. A flow controller **80** may be provided within the air return pathway **64** to direct flow through an air return pathway **84** that exhausts into the refrigerator compartment or an air return pathway **82** that exhausts into the freezer compartment **16**. The present invention contemplates that other pathways may be configured so that air from the air return pathway **64** is communicated to other locations within the cabinet body of the refrigerator **12**. For example, the air within the air return pathway **64** may be communicated to a discreet (e.g., modulated space or bin), or desired space within the refrigerator compartment **14** or freezer compartment **16**. A separate cabinet, bin or module within the freezer compartment **16** or refrigerator compartment **14** may be configured to receive air exhausted from the thermoelectric device **50** through the air return pathway **64**. A junction may be provided in the air supply pathway **62** at the interface between the refrigerator compartment door **18** and the refrigerator compartment **14**. The interface (not shown) between the refrigerator compartment **14** and refrigerator compartment door **18** is sealed and separated upon opening and closing the refrigerator compartment door **18**. Alternatively, the air supply pathway **62** may be configured through another attachment or interface point of the refrigerator compartment door **18** such as a hinge point at a top or bottom portion of the door. Thus, cool air from the refrigerator compartment **14** is communicated through the air

5

supply pathway 62 to the air sink 56 of the thermoelectric device 50. The air temperature in the refrigerator compartment 14 ranges generally between 32° Fahrenheit and about 40° Fahrenheit and the temperature on the cold side 54 of the thermoelectric device 50 ranges anywhere from about 32° Fahrenheit to 40° Fahrenheit minus the temperature delta of the thermoelectric device. Assuming the refrigerator compartment is set at 35° Fahrenheit and the thermoelectric device has a delta of 10 degrees, the cold side 54 of the thermoelectric device 50 would operate generally at 25° Fahrenheit. The liquid in the fluid supply pathway 110 is cooled generally then to the temperature of the cold side 54 of the thermoelectric device 50. Heat from the ice mold 106 is extracted and carried away from the icemaker 102 through the fluid return pathway 112. Depending upon the desired rate of production of ice, the flow rate of fluid through the fluid supply pathway 110 and the flow rate of air through the air supply pathway 62 may be controlled so that the warm side 52 and cold side 54 of the thermoelectric device 50 are kept at the desired operating temperatures so that ice production can be maintained at a desired rate of production by extracting heat from the ice mold 106 of the icemaker 102 at a rate that is capable of sustaining the desired level of ice production. The rate of operation for these various components may be controlled to use the least amount of energy necessary for keeping up with the desired rate of ice production.

As illustrated in FIG. 4, the air sink 56 may include a plurality of fins to allow heat to be dissipated from the warm side 52 of the thermoelectric device 50 using air from the refrigerator compartment 14 to pass through the air supply pathway 62 and return to the refrigerator compartment or freezer compartment through the air return pathway 64. The fluid in the fluid supply pathway 110 and fluid return pathway 112 may be communicated through the fluid sink 58 and the ice mold 106 by actuation of a pump 66. The ice mold 106 may include a number of aqueducts or channels for passing fluid through for cooling the ice mold or extracting heat from the ice. Using fluid to cool the ice mold 106 allows various types of icemakers to be used, such as a flex-tray icemaker. The icemaker 102, ice storage bin 104, and thermoelectric device 50 may be mounted together in a configuration to form an icemaker module 28. The icemaker module 28 may be configured on the refrigerator compartment door 18 as shown in FIG. 4.

FIG. 5 illustrates other exemplary aspects for one or more configurations of the present invention. The door illustrated in FIG. 5 may be a refrigerator compartment door 18 such as illustrated in FIGS. 1A, 2 and 3. The various components making up the icemaker module 28 (illustrated in FIG. 5) may be housed within an insulated compartment 108 such as illustrated in FIG. 2. As previously illustrated and described, the thermoelectric device 50 includes an air sink 56 configured to receive air through an air supply pathway 62 connected between the thermoelectric device 50 and a fan 60 in the refrigerator compartment 14 of the refrigerator 10. Air passing through the air sink 56 dissipates heat from the warm side 52 of the thermoelectric device 50. The warm air is communicated through an air return pathway 64 to the refrigerator compartment 14 and/or freezer compartment 16. A flow controller 70 may be configured in the air return pathway 64 for selectively controlling the flow of warm air there through. According to one aspect of the invention, warm air may be communicated through an air supply pathway 68 connected between the flow controller 70 and the ice maker 102. Ductwork or other channels of communication may be provided within the refrigerator compartment door 18 or within the insulated compartment 108 for communicating air between

6

the flow controller 70 and the icemaker 102. Advantageously, during an ice harvesting cycle, warm air from the air sink 56 may be communicated through air supply pathway 68 to the ice mold 106 to assist in the ice harvesting process whereby the ice mold 106 is warmed to a temperature to create a thin fluid layer between the frozen ice and the side walls of the ice mold to allow each of the cubes to release from the ice mold during harvesting. One or more ducts or channels may be configured within the ice mold 106 to direct the flow of warm air within the air supply pathway 68 to specific regions or locations within the icemaker. The air supply pathway 68 may also be configured to communicate warm air through one or more ducts positioned adjacent to or in contact with the ice mold 106 for warming the ice mold 106 by convection or conduction.

In addition to cooling the ice mold 106, the fluid supply pathway 110 originating at the fluid sink 58 of the thermoelectric device 50 may be configured with a flow controller 116 for selectively communicating the cold fluid through the ice storage bin 104 (e.g., the sidewalls of the ice storage bin). For cooling the ice storage bin 104, a flow controller 116 may also be included in the fluid return pathway 112 for controlling liquid flow through the fluid return pathway 112 into the fluid sink 58. The flow controllers 116 may be operated to allow both cooling of the ice mold 106 and the ice storage bin 104 simultaneously to the extent the demand on the thermoelectric device 50 does not exceed its capabilities. Thus, the ability to extract heat using air from the refrigerator compartment for cooling the thermoelectric device 50 may be used to provide other cooling operations on the refrigerator compartment door as illustrated in FIG. 5.

FIG. 6 illustrates another possible cooling application according to an exemplary aspect of the present invention. Beneficially, aspects of the present invention, such as those illustrated in FIG. 6, provide for both cooling and heating applications on, for example, a refrigerator compartment door 18 of a refrigerator 10. The cooling and heating applications may also be included as components or subcomponents of the icemaker module 28. As indicated previously, the thermoelectric device 50 has a warm side 52 and a cold side 54. The cold side is in thermal contact with the fluid sink 58 and the warm side is in thermal contact with the air sink 56. Reversing the polarity of the thermoelectric device 50 changes the warm side 52 to a cold side and the cold side 54 to a warm side. The thermoelectric device 50 may be operated in two modes, namely the mode illustrated in FIG. 6 and in a mode where the warm and cold sides are switched. In the mode illustrated in FIG. 6, the cold side 54 is in thermal contact with the fluid sink 58 and the warm side 52 is in thermal contact with the air sink 56. A fluid supply pathway 110 is connected between the icemaker 102 and the fluid sink 58. A flow controller 120 in the fluid supply pathway 110 is selectable between open and closed positions. A fluid supply pathway 118 is connected between the fluid supply pathway 110 and the fluid return pathway 112 by a flow controller 120. The fluid supply pathway 118 is connected to a warming or cooling application 124. Thus, the fluid supply pathway 110 may be used to supply cold fluid to the cooling application 124 via fluid supply pathway 118 by selectively changing the flow controller 120 in both the fluid supply pathway 110 and fluid return pathway 112. The warming or cooling application 124 may include a reservoir housing a body of liquid. The liquid in the reservoir may be supplied to the icemaker 102 through supply pathway 88 or supplied to the refrigerator 10 through supply pathway 86 for dispensing from the dispenser 22. Cooling liquid passed through the cooling application 124 cools the reservoir of liquid which may then be communi-

7

cated to other applications, such as for example, applications on or remote from the refrigerator compartment door 18 that uses cool or chilled liquid. For example, the chilled liquid from the cooling application 124 may be communicated to the icemaker 102 for use in the ice mold 106 to reduce the amount of energy and time to make ice. If the cooling fluid within the fluid supply pathway 118 is at a temperature of 38 to 40 degrees Fahrenheit the water in the reservoir in the cooling application 124 may be cooled generally to the same temperature and communicated to the ice mold 106, which can reduce the amount of time and energy used to freeze the water. Cooling application 124 may also be used to cool water that is communicated to the dispenser 22 for dispensing cold water from the refrigerator 10. The chilled water may also be used to provide cooling within the refrigerator compartment 14 by communicating the chilled water across the door 18 into the compartment 14. For example, the chilled liquid may be used for controlling or assisting with the temperature control of a bin, drawer or other defined space. Reversing the polarity of the thermoelectric device 50 cools the air passing through the air return pathway 64 back to the refrigerator compartment 14 or freezer compartment 16 and warms the fluid sink 58. The fluid in the fluid supply pathway 118 may be then used to warm the water within the heating application 124. The warm water within the heating application 124 may be communicated to the dispenser 22 on the refrigerator 10 for dispensing warm water or may be used by the icemaker 102 for ice harvesting or for performing a wash, sanitizing or recycle of the ice mold 106. The warm water may also be communicated to the refrigerator compartment 14 across the door 18 for controlling or assisting with the temperature control of a drawer, bin, or other defined space within the refrigerator compartment 18.

FIG. 7 illustrates another exemplary configuration contemplated by various aspects of the present invention. The icemaker module 28 may be configured to include other applications in addition to those described above. As indicated previously, the thermoelectric device 50 may be used to support not only primary cooling applications but secondary and possibly tertiary cooling applications or heating applications. FIG. 7 illustrates another exemplary cooling application according to one aspect of the present invention. As the fluid sink 58 is maintained at a temperature minus delta below the air temperature passing through the air supply pathway 62, the fluid sink 58 may be used to provide cooling to various applications, such as, on the door 18 of the refrigerator compartment 14. A reservoir 130, for example, may be provided for housing a body of water to be used for dispensing from the dispenser 22 or used in the icemaker 102 for making ice. Heat may be extracted from the reservoir 130 by placing the reservoir 130 in thermal contact with the fluid sink 58. A supply pathway 86 and 88 may be connected between the dispenser 22 and the reservoir 130 and the icemaker 102 and the reservoir 130 for providing chilled water to either or both. The chilled water may also be used to provide cooling within the refrigerator compartment 14 by communicating the chilled water across the door 18 into the compartment 14. For example, the chilled liquid may be used for controlling or assisting with the temperature control of a bin, drawer or other defined space. As previously indicated, the fluid return pathway 112 carries heat away from the ice mold 106. Beneficially, the heat carried in the fluid return pathway 112 may be used in the ice storage bin 104 for melting ice within the bin 104 for creating fresh or clear ice. A fluid supply pathway 126 may be configured within the ice storage bin 104 (e.g., within the walls of the ice storage bin) for warming the ice within the ice storage bin 104. The fluid supply pathway may be con-

8

figured between flow controllers 128 which are selectably open and closed to allow or provide for warm fluid flow through the fluid supply pathway 126 within the ice storage bin 104. As the fluid passes through the fluid supply pathway 126 the ice within the ice storage bin 104 is warmed and begins to melt and thereby creates fresh ice. The fluid within the fluid supply pathway 126 is cooled and returned to the fluid sink 58 through the fluid return pathway 112. The fluid may also enter the fluid sink 58 from the fluid return pathway 112 at a temperature lower than the fluid that returns from the ice mold 106 during the ice making process. Thus, the thermoelectric device 50 requires less energy to cool the fluid in the fluid supply pathway 110. As with the warming application 124 shown in FIG. 6, the warmed water in the reservoir 130 may also be communicated to the refrigerator compartment 14 across the door 18 for controlling or assisting with the temperature control of a drawer, bin, or other defined space within the refrigerator compartment 18.

FIG. 8 illustrates another exemplary aspect of the present invention. As previously indicated, an air supply pathway 62 feeds air from the refrigerator compartment 14 to the thermoelectric device 50. According to one aspect of the invention, a flow controller 74 may be configured in the air supply pathway 62 for selectively controlling the flow of air through the pathway. The air in the air supply pathway 62 is generally at the temperature of the refrigerator compartment 14 (i.e., generally between 32° Fahrenheit and 40° Fahrenheit). An air supply pathway 72 may be configured between the ice storage bin 104 and the flow controller 74 whereby air from the refrigerator compartment may be communicated to the ice storage bin 104 for cooling the ice in the ice storage bin. Alternatively, a flow controller 78 may be included in the air return pathway 64 for selectively controlling the flow of air through an air supply pathway 76. The air supply pathway 76 may be connected between the ice storage bin 104 and the flow controller 78 for communicating warm air to the ice storage bin 104 for melting or warming the ice for providing a fresh ice or clear ice product.

FIGS. 1B, 1C and 1D illustrate a refrigeration platform 10 configured with one or more aspects of the invention. In FIG. 1B, a water dispenser or water cooler (i.e. refrigeration platform 10) includes a dispenser 22 for water housed in a cabinet body 12. The cabinet body 12 may also be configured with an ice maker module 28, such as one of the modules illustrated in FIGS. 4-8. Using any one of the ice maker modules 28 illustrated in the Figures, the water cooler or water dispenser may be configured to dispense ice using an ice making process assisted by a thermal electric device. Similar to the refrigerator platform, heat from off the warm side of the thermal electric device may be extracted using cool air or liquid taken from the refrigeration process used to chill the liquid being dispensed from the dispenser 22. Therefore, the same concepts described above relating to implementation into a refrigerator apply here with implementation into a water dispenser or water cooler. FIG. 1C illustrates another aspect of the invention. In FIG. 1C an ice maker module 28, such as those illustrated in FIGS. 4-8, may be configured into an under cabinet refrigeration platform 10. The under cabinet refrigeration platform 10 includes a cabinet body 12 for housing the ice maker module 28. The cabinet body 12 may be positioned underneath the counter top 24 and/or alongside a cabinet 26. The ice maker module 28 may be used to provide ice at an under cabinet location using an ice maker assisted by a thermal electric device. Ice may be delivered through a door on the cabinet directly from the ice mold or from an ice storage bin. Ice may also be retrieved from the cabinet body 12 through a door in covering relation to the icemaker, ice

storage bin or cabinet body **12**. Similar to the refrigerator platform **10** illustrated in FIG. **1C**, a refrigerator platform **10** may be configured with one of the ice maker modules **28** shown in FIGS. **4-8**. The refrigeration platform **10** may be a countertop dispenser configured for resting atop a counter **24** supported, for example, by one or more cabinets **26**. The counter top refrigeration platform **10** may include a cabinet body **12** for housing the ice maker module **28**. The ice maker module **28** may be configured to provide ice within the cabinet body **12** or delivered through a door using an ice maker assisted by a thermal electric device.

In still another aspect of the invention, the thermal electric device **50** may be configured with a cold side **54** and a warm side **52**. An air sink **56** may be configured in thermal contact with the warm side **52** of the thermal electric device **50**. Ambient air may be used to extract heat off of the air sink **56** and the warm side **52** of the thermal electric device **50**. Thus, in one aspect, the thermal electric device **50** may be configured to provide cooling at the cold side **54** without bringing air to the air sink **56** from the refrigeration compartment. For example, the size and performance characteristics (e.g., operating efficiency) of the thermal electric device **50** may be selected so that the air sink **56** is capable of extracting enough heat from the warm side **52** of the thermal electric device **50** to provide a cold side **54** at the desired operating temperatures. In instances where the refrigeration platform **10** does not include refrigeration components (e.g., compressor, condenser, evaporator) the thermal electric device **50** may be configured to operate without the assistance of bringing cool air from the refrigerator compartment or freezer compartment to the air sink **56** for extracting heat from the warm side **52** of the thermal electric device **50**. For example, in FIG. **1C** and FIG. **1D** a refrigerator platform **10** is shown. The platform may not include components for providing refrigeration (i.e. compressor, condenser, evaporator), and therefore, the thermal electric device **50** may be configured to radiate a sufficient amount of heat from the warm side **52** to provide a cold side **54** at the desired temperatures for operating an ice maker within a cabinet body **12** that does not include the aforementioned refrigeration components.

FIG. **9** provides a flow diagram illustrating one or more of the control processes of the present invention. To perform one or more aforementioned operations or applications, the refrigerator **10** may be configured with an intelligent control **200** such as a programmable controller. A user interface **202** in operable communication with the intelligent control **200** may be provided, such as for example, at the dispenser **22**. A data store **204** for storing information associated with one or more of the processes or applications of the refrigerator may be configured in operable communication with the intelligent control **200**. A communications link **206** may be provided for exchanging information between the intelligent control **200** and one or more applications or processes of the refrigerator **10**. The intelligent control **200** may also be used to control one or more flow controllers **208** for directing flow of a heat carrying medium such as air or liquid to the one or more applications or processes of the refrigerator **10**. For example, in an ice making application **210** the flow controller **208** and intelligent control **200** control and regulate the air flow **214** from the refrigerator compartment **14** to the thermoelectric device process **212**. The thermoelectric device process **212** controls the temperature **216** of the fluid flow **218** to the ice making process **210**. The rate at which the air flow **214** moves air from the refrigerator compartment **14** to the thermoelectric device process **212** for controlling the temperature **216** may be controlled using the intelligent control **200** in operable communication with one or more flow controllers **208**.

The rate of fluid flow **218** to the ice making process **210** may also be controlled by the intelligent control **200** operating one or more flow controllers **208**. For example, the air flow process **214** may be provided by intelligent control **200** of a fan or other pump mechanism for moving air flow from the refrigerator compartment **14** to the thermoelectric device process **212**. The intelligent control **200** may also be used to control the pump used to control fluid flow **218** from the thermoelectric device process **212** to the ice making process **210**. The rate at which the pump and the fan operate to control air flow **214** and fluid flow **218** may be used to control the temperature **216** depending upon the rate of the ice making process **210**. The intelligent control **200** may also be used to control the ice harvesting process **220**. One or more flow controllers **208** under operation of the intelligent control **200** may be used to control air flow **224** to the thermoelectric device process **222** and fluid flow **228** to the ice harvesting process **220**. For example, the intelligent control **200** may be used to reverse polarity of the thermoelectric device process **222** to increase the temperature **226** of the fluid flow **228** to enable the ice harvesting process **220**. Intelligent control **200** may also be used to control one or more flow controllers **208** to increase the temperature **226** of the air flow **224** and communicating the air flow **224** to the ice harvesting process **220** for warming the ice mold and harvesting the ice. The temperature **226** of the fluid flow **228** and/or the air flow **224** may be controlled using the thermoelectric device process **222** for warming ice within the ice bin to provide a fresh ice product or a clear ice product depending upon an input at the user interface **202**. In another aspect of the invention, the intelligent control **200** may be used to control cooling and heating applications **230**, such as for example, on the refrigerator compartment door **18** of the refrigerator **10**. A reservoir of water may be provided that is chilled or heated by control of the intelligent control **200**. The temperature **236** of the water in the cooling or heating application **230** may be controlled by controlling the fluid flow **238** and/or air flow **234** from the thermoelectric device process **232** to the cooling or heating application **230**. One or more flow controllers **208** under operable control of the intelligent control **200** may be operated to perform the cooling or heating application **230**. For example, the thermoelectric device process **232** may be used to lower the temperature **236** of the fluid flow **238** to the cooling application **230**. Alternatively, the temperature **236** of the fluid flow **238** may be increased using the thermoelectric device process **232** for providing heating at the heating application **230**. Air flow **234** from the refrigerator compartment **14** may also be used to provide cooling or heating. The air flow **234** to the thermoelectric device process **232** may be used for the cooling application or the heating application **230**. For example, the air return pathway from the thermoelectric device process **232** increases the temperature **236** at the heating application **230**. Alternatively, the air flow **234** to the thermoelectric device process **232** may be used to decrease the temperature **236** at the cooling application process **230**. Intelligent control **200** may also be configured to control the ice bin process **240**. One or more flow controllers **208** under operable control of the intelligent control **200** may be used to control air flow **244** and/or fluid flow **248** to the ice bin process **240**. The temperature **246** of the fluid flow **248** to the ice bin process **240** or the temperature of air flow **244** from the refrigerator compartment **14** to the ice bin process **240** may be controlled using one or more flow controllers **208**. The thermoelectric device process **242** may be configured to provide a fluid flow **248** to the ice bin process **240** having a lower temperature **246** or a fluid flow **248** to the ice bin process **240** having a warmer temperature **246**. Air flow **244** to the thermoelectric device

11

process 242 may also be used to cool or warm the ice bin process 240. Air flow 244 from the refrigerator compartment may be used to cool the ice bin process 240 whereas air flow 244 from the thermoelectric device process 242 may be used to warm the ice bin process 240. Thus, the temperature 246 of fluid flow 248 or air flow 244 may be controlled using the intelligent control 200 in operable communication with one or more flow controllers 208 for controlling the ice bin process 240. For example, the fluid flow 248 from the thermoelectric device process 242 to the ice bin process 240 may be controlled using one or more flow controller 208 under operation of the intelligent control 200 whereby the temperature 246 of the fluid flow 248 is used in a cooling ice bin process 240 or warming ice bin process 240. Thus, one or more methods for controlling the temperature of one or more applications, such as for example, an ice making process on a refrigerator compartment door, are provided.

The foregoing description has been presented for the purposes of illustration and description. It is not intended to be an exhaustive list or limit the invention to the precise forms disclosed. It is contemplated that other alternative or exemplary aspects are considered included in the invention. The description is merely examples of embodiments. For example, the exact location of the thermoelectric device, air or fluid supply and return pathways may be varied according to type of refrigerator used and desired performances for the refrigerator. In addition, the configuration for providing heating or cooling on a refrigerator compartment door using a thermoelectric device may be varied according to the type of refrigerator, dispenser, or refrigeration platform. It is understood that any other modifications, substitutions, and/or additions may be made, which are within the intended spirit and scope of the invention. From the foregoing, it can be seen that the invention accomplishes at least all of the intended objectives.

What is claimed is:

1. A refrigerator that has a fresh food compartment, a freezer compartment, and a door that provides access to the fresh food compartment, the refrigerator comprising:

an icemaker mounted remotely from the freezer compartment, the icemaker including an ice mold;

a thermoelectric device positioned remotely from the ice mold within the fresh food compartment, the thermoelectric device having a warm side and opposite cold side;

a liquid flow pathway in communication between the cold side of the thermoelectric device and the icemaker;

a fan positioned to move air from the fresh food compartment across the warm side of the thermoelectric device.

2. The refrigerator of claim 1 further comprising an air return pathway in communication between the thermoelectric device and the fresh food compartment for exhausting air from the thermoelectric device to the fresh food compartment.

3. The refrigerator of claim 1 further comprising an air return pathway in communication between the thermoelectric device and the freezer compartment for exhausting air from the thermoelectric device to the freezer compartment.

4. The refrigerator of claim 1 further comprising an air return pathway in communication between the thermoelectric device and the icemaker for exhausting warm air from the thermoelectric device to the icemaker during an ice harvesting cycle.

5. The refrigerator of claim 1 further comprising an air return pathway in communication between the thermoelectric device and a water reservoir or line for supplying warm water at a water dispenser.

12

6. The refrigerator of claim 1 further comprising an air supply pathway in communication between the thermoelectric device and the fresh food compartment for supplying cold air to the thermoelectric device.

7. The refrigerator of claim 1 wherein flow pathway comprises a liquid loop in communication between the thermoelectric device and the icemaker for supplying cold liquid to the ice mold.

8. The refrigerator of claim 7 further comprising a pump positioned to move liquid from the thermoelectric device to the icemaker.

9. The refrigerator of claim 1 further comprising a heat exchange interface between the liquid flow pathway and a water reservoir or line for supplying:

- a. warm water at a water dispenser;
- b. chilled water at a water dispenser;
- c. chilled water at the icemaker.

10. The refrigerator of claim 1 further comprising a heat exchange interface between the liquid flow pathway and:

- a. a cooling application on the door;
- b. a warming application on the door.

11. The refrigerator of claim 1 further comprising: an insulated compartment on the door; an ice storage bin in the insulated compartment positioned to receive ice harvested from the ice mold; and the liquid flow pathway in communication between the insulated compartment and the thermoelectric device for cooling the insulated compartment.

12. The refrigerator of claim 1, wherein the icemaker is mounted on the fresh food compartment door.

13. A refrigerator that has a fresh food compartment, a freezer compartment, and a door that provides access to the fresh food compartment, the refrigerator comprising:

an icemaker mounted remotely from the freezer compartment, the icemaker including an ice mold;

a thermoelectric device disposed remotely from the ice mold within the fresh food compartment, the thermoelectric device having a warm side and opposite cold side;

a pump positioned to move a liquid from the cold side of the thermoelectric device to the icemaker;

a fan positioned to move air from the fresh food compartment across the warm side of the thermoelectric device.

14. The refrigerator of claim 13 further comprising an air return pathway in communication between the thermoelectric device and the fresh food compartment for exhausting air from the thermoelectric device to the fresh food compartment.

15. The refrigerator of claim 13 further comprising an air return pathway in communication between the thermoelectric device and the icemaker for exhausting warm air from the thermoelectric device to the icemaker during an ice harvesting cycle.

16. The refrigerator of claim 13 further comprising: a water reservoir or line for supplying warm water at a water dispenser;

an air return pathway in communication between the thermoelectric device and the water reservoir or line.

17. The refrigerator of claim 13 further comprising an air supply pathway in communication between the fresh food compartment and the thermoelectric device for supplying cold air to the thermoelectric device.

18. The refrigerator of claim 13 further comprising a liquid supply pathway in communication between the thermoelectric device and the icemaker for supplying cold liquid to the icemaker.

13

19. The refrigerator of claim **18** further comprising a heat exchange interface between the liquid supply pathway and a cooling application on the door.

20. The refrigerator of claim **13** further comprising a liquid return pathway in communication between the icemaker and the thermoelectric device. 5

21. The refrigerator of claim **20** further comprising a heat exchange interface between the liquid return pathway and a warming application on the door.

22. The refrigerator of claim **18** further comprising: 10
an insulated compartment on the door;
an ice storage bin in the insulated compartment positioned to receive ice harvested from the ice mold; and
the liquid supply pathway in communication between the thermoelectric device and the insulated compartment for 15
cooling the insulated compartment.
